# MORTALITY EXPERIENCE OF DI DISABLED WORKERS AND SSI DISABLED ADULTS WITH HIV-RELATED IMPAIRMENTS, 2002-06 

by Tim Zayatz and Nettie Barrick

## Introduction

The first awards from the Social Security Disability Insurance (DI) and Supplemental Security Income (SSI) programs to persons disabled by Acquired Immunodeficiency Syndrome (AIDS) were made in 1982. Since that time, the Social Security Administration has monitored the magnitude of HIVrelated DI and SSI disabled adult program expenditures and made projections of future expenditures.

These expenditures are a function of the numbers of persons disabled by Human Immunodeficiency Virus (HIV) and the length of time they remain on the rolls. Because death is the primary reason for termination of benefits payable to HIV beneficiaries, their mortality more-or-less determines the amount of time spent on the rolls. This actuarial note focuses on our most recent examination of DI and SSI administrative records consisting of about 881,000 life-years of exposure of HIV-related cases during the 5-year period 2002-06.

For comparison, we also include selected results from Actuarial Note Death Termination Experience for DI Disabled Workers and SSI Disabled Adults with HIV-Related Impairments (June 2005). ${ }^{1}$ This prior study examined HIV experience over two separate 5 -year periods: 1992-96 and 19972001. The current study uses the same methods as the prior study, the details of which are presented in Appendix A.

## SSA History of HIV Identification

The agency's collection of administrative data that provide the basis for this study was developed over time. As the medical world gained a greater understanding of the effects of HIV on diverse body systems, SSA also progressed in evaluating disability claims based on the presence of the infection.

The SSA-831 is the record of a disability determination by the State Disability Determinations Services. On this record, the adjudicator enters the primary and secondary diagnoses and numerical codes. The primary diagnosis specifies the principal disabling condition. The secondary diagnosis is generally the condition next in severity, and allows us to identify additional cases where HIV is a contributing (if not the primary) reason for impairment. For the most part, the beneficiaries in our HIV database have been identified from these codes.

[^0]However in the early years of the epidemic, there were no codes specific for HIV. The oldest cases in our database were identified by manually examining claims folders when the diagnosis was one that might be HIV-related. This slow manual process could not accommodate the explosion of HIV cases. Accordingly, the administration selected a set of diagnoses where-based on experiences of the manual processHIV was likely to be involved. Infected persons who filed for benefits as a result of impairments related to general immune deficiency, or two diseases in particular-Kaposi's sarcoma and pneumocystis carinii pneumonia-were among the first to receive an HIV-related diagnosis.

In the Ninth Revision of the International Classification of Diseases, effective 1987, the World Health Organization established ICD series 042.0-044.9 specifically for HIVrelated diseases, ${ }^{2}$ and SSA followed with a corresponding series of impairment codes. As a result, the collection of data shifted to identifying new cases using the now-familiar HIV diagnosis codes of 042,043 , and 044 , while continuing to track the experience of HIV cases that had been identified under prior evaluations.

Since 1990, our process for collecting HIV data has remained relatively unchanged. Every six months, administrative data on previously identified cases is updated, and newly-identified HIV beneficiaries are added to the data collection. Code 043 may be used as the primary or secondary diagnosis code where symptomatic HIV infection is accompanied by symptoms reasonably assumed to be related to the infection. Code 044 is used when asymptomatic HIV is involved either as a primary or secondary reason for allowance. Code 042 was used primarily for cases involving AIDS and AIDS-related Complex; beginning in December 2004, 042 became associated with neoplastic malignancies and is no longer used to identify HIV-related impairments.

## Evaluation and Early Projections

In addition to changes in the way we have collected data on HIV cases, the standards used to evaluate HIV disability claims have also changed over time. In the early years of the virus, SSA remained consistent with the identification process set forth by the Centers for Disease Control and Prevention (CDC) and World Health Organization. As the epidemic pro-

[^1]gressed in severity, the agency found it necessary to define its own guidelines for evaluating HIV-related impairments in order to administer the DI and SSI programs.

A broader knowledge of the infection made it clear that some progressive and seriously disabling conditions were not included in the early definition of AIDS. Clinicians began to identify a group of individuals with a variety of signs and symptoms which were thought to be caused by the virus. The collection of these symptoms came to be known as AIDSRelated Complex (ARC). ${ }^{3}$ Effective September 1987, the CDC began using revised criteria for determining which cases involving HIV should be reported for AIDS statistical surveillance purposes. The revision expanded the definition to include HIV Dementia and Wasting. To remain consistent, SSA revised its definition for AIDS, but discontinued the automatic link with the CDC definition. The revised criteria led to reclassifying as AIDS a number of then-current beneficiaries who were on the disability rolls due to ARC, rather than a definitively diagnosed case of AIDS. This contributed to the number of AIDS-related impairments on the DI rolls which grew rapidly from 5,700 at the end of 1986 to 17,400 by the end of 1988.

In 1990, SSA re-issued guidelines to include criteria for symptomatic HIV, including all lymphomas and other disease manifestations coupled with 200 CD4 count and marked functional limitations. The expanded guidelines more clearly defined the aspects of disability for individuals who had HIV, but had not progressed to the point of having AIDS and resulted in a new class of HIV impairments. By 1992, the DI program had experienced its most critical year for new HIV entitlements as an additional 33,000 workers began receiving payments. By the end of the year there were 61,000 AIDSrelated impairments on the DI rolls. In June 1993 HIV was split out from the infectious/parasitic category and received its own regulatory listing in the Listing of Impairments. ${ }^{4}$

Around this time, with the epidemic seemingly out of control, actuarial models predicted that the number of DI disabled workers with HIV/AIDS would more than double by 1999 to 131,000-including 60,000 new entitlements in that year alone-and annual benefit payments would rise to $\$ 1.3$ billion. Although the rolls did experience an elevated number of HIV awards through 1996, the effects were somewhat muted since HIV mortality was so high that monthly benefit payments were often made only for a relatively short period of time, if at all. Many never received payments, failing to survive the required 5-month waiting period under the DI pro-

[^2]gram. One-third of those who made it onto the rolls had died by the end of the calendar year in which they became entitled; two-thirds had died by the end of the following year. As it turned out, by 1999, the DI program paid an estimated \$900 million in benefits to about 95,000 HIV beneficiariesincluding 11,500 new entitlements in that year. Recent data indicate that in 2011, an estimated $\$ 1.8$ billion in DI benefits was paid to roughly 137,000 HIV beneficiaries-including 10,000 new entitlements. An additional 55,900 received an estimated \$528 million in Federal SSI-only payments. ${ }^{5}$

## HIV/AIDS Mortality Experience

The experience covered in this study is not comparable to the mortality experience of the HIV/AIDS population being monitored by CDC. ${ }^{6}$ The number of individuals awarded DI or SSI disability benefits based at least in part on HIV infection, is only a fraction of those diagnosed. In essence, we study persons for whom the infection has progressed to the point of being disabling. Many others remain in the work force for an extended period of time and may never file a claim. Still others may lack insured status or have excess income or resources, which preclude them from receiving benefits. So on average, disabled beneficiaries with HIV impairments will be less healthy than the HIV population tracked by CDC. Also, while CDC measures mortality from the point of diagnosis, our study measures it from the date of entitlement to benefits. In general, these two dates are likely to be very different.

## Summary of HIV Experience (1992-96) ${ }^{7}$

CDC tracking shows that AIDS incidence in the general population peaked in 1993, and the estimated number of deaths among persons with AIDS increased steadily through 1994. During 1992-96, there were approximately 143,000 new HIV beneficiaries and 145,700 death terminations from the DI and SSI rolls. The number of beneficiaries that appeared on the disability rolls with HIV as the primary diagnosis for impairment was greater than those for whom HIV was a secondary diagnosis by a ratio of 10-to-1. The ratio of symptomatic HIV to asymptomatic HIV cases was roughly 6-to-1. Data suggest that cases having HIV impairment as the primary diagnosis, or symptomatic HIV diagnosis exhibit inherently higher mortality than cases having secondary or asymptomatic HIV diag-

[^3]nosis. These factors had a significant impact on HIV disability with regard to the number of new entitlements, the amount of time spent on the rolls, and the number of deaths.

## Summary of HIV Experience (1997-2001)

By 1996, CDC began reporting sharp declines in AIDS incidence as a result of public awareness and widespread use of highly-active antiretroviral therapy (HAART) which slows the reproduction of the virus and the progression of HIV infection to AIDS. By 1998, CDC reported a leveling of incidence and essentially no change from 1999 to 2001 with roughly 41,000 new AIDS cases reported nationally each year over that period. DI entitlements followed the decline in population incidence as infected workers remained employed for longer periods of time. Since peaking at 33,000 in 1992, the number of workers becoming entitled to DI benefits based on HIV fell to roughly 11,000 annually by 2001. During 199701 , there were approximately 59,000 new HIV beneficiaries and 58,400 death terminations from the DI and SSI rolls.

Dramatic differences in mortality emerged during this period. When compared to the earlier 5-year period, HIV mortality among males for 1997-2001 was 50-70 percent lower for early durations, and 25-50 percent lower for later durations. Similar declines occurred among females.

Much of the decline in mortality experience among DI and SSI recipients appears to be consistent with the wider use of HAART and, to a lesser extent, differences in the composition of the rolls-that is, compared to the 1992-96 period, the distribution of primary-to-secondary diagnosis dropped to less than 7 -to-1; and the ratio of symptomatic-to-asymptomatic cases dropped to 4-to-1.

## HIV Experience (2002-06)

This study is dedicated to HIV mortality experience for the DI and SSI rolls over the period 2002-06. CDC reported that there were 442,000 persons living with AIDS in the U.S. as of the end of 2006; an estimated 36,000 new cases occurred nationally that year (roughly 12.1 per 100,000 population). From the beginning of the epidemic through 2006, CDC estimates that 976,300 cases had been diagnosed and 547,600 persons had died with AIDS in the U.S. ${ }^{8}$

SSA records indicate that there were 121,000 HIV worker beneficiaries on the DI rolls at the end of 2006, with an estimated 54,000 new entitlements occurring over 2002-06. ${ }^{9}$ Additionally, an estimated 53,300 individuals were receiving SSI benefits because of the virus. ${ }^{10}$ Over the same period, the DI and SSI rolls experienced approximately 52,700 death ter-

[^4]minations of HIV beneficiaries. Note that deaths of persons with a diagnosis of HIV infection may be due to any cause (that is, may or may not be related to HIV).

Major findings of this study include:
AIDS mortality is high. Compared to the experience of DI workers overall for the period 2001-05, HIV mortality is 50 to 200 percent higher at most attained ages for males, and 100 to 300 percent higher for females. ${ }^{11}$ We do, however, continue to see improvement. Compared to our last study of HIV mortality over the period 1997-2001, the probability of death among males for 2002-06 is 22 percent lower on average for durations $0-5$ and 14 percent lower for durations 6-10. For females, the average reduction ranges from 20 percent in earlier durations to 5 percent in later durations.

Gender differences are less distinct. The familiar female advantage in mortality is very slight among HIV beneficiaries. In fact, female mortality is higher than males for about 40 percent of all attained ages. In the general disability population, this occurs less than 3 percent of the time.

Demographic factors are less evident. In general, a disabled beneficiary's attained age largely influences mortality in later durations. The smooth age gradient that is noticeable in the overall disability population is not evident among the HIV population, which shows much fluctuation from one duration to the next. We suspect this behavior is influenced by the fact that we simply don't know how long individuals have been infected or the degree of therapy that has been received.

Mortality among SSI recipients is likely worse. The combined DI/SSI mortality experience is worse than the DI mortality experience. This likely reflects a socioeconomic differential in mortality, considering that the SSI program is means-tested. In particular, some low-income persons may lack the means to obtain medical treatment that would improve their prognosis.

## List of Tables

The data are presented in a set of comprehensive tables, in which various measures of mortality and survival are given for ages 18 to 65 and durations 0 to 10. In cells where the data are sparse, particularly for the younger ages, the values are subject to significant random fluctuation. Where the data are very sparse, we sought to mitigate the problem by using blending and graduation techniques.

Table 1A and Table 1B show probabilities of death for male and female disabled beneficiaries with HIV-related impairments, by select age and duration since entitlement. Results

[^5]are based on the combined experience of the DI and SSI rolls from January 1, 2002 through December 31, 2006. The probability of death among HIV beneficiaries is generally highest within the first several durations.

Table 2A and Table 2B show the number of survivors remaining at different durations from cohorts becoming entitled at various ages. These tables are based on the probabilities of death shown in tables 1A and 1B. These survival tables make it easy to calculate the probabilities of surviving a given number of years. Appendix A provides details on table construction and usage.

Table 3A and Table 3B show the expected future lifetime of HIV- disabled beneficiaries, based on the survivorship experience shown in tables 2A and 2B. Life expectancy is greater in the second year of entitlement than in the first year because of higher mortality during the first year on the rolls.

Table 4 shows the aggregate probability of death and expected future lifetime, by select age. Table 5 shows the aggregate probability of death and expected future lifetime, by attained age. Probabilities are based on aggregate counts of exposure and deaths across all durations. They represent the average probability of death within the next year for those originally entitled at a particular select age, or who have attained a particular age, respectively.

Similarly, expected future lifetime represents the average life expectancy of those who share a particular select or attained age, respectively. Values are exposure-weighted averages of the select-and-ultimate future lifetimes shown in tables 3A and 3B and may be used as a general indication of the overall average future lifetime of a particular entitlement cohort (table 4), or a group of beneficiaries from various entitlement cohorts who have attained a particular age (table 5).

Table 6 shows the aggregate probability of death and expected future lifetime, by duration (years since selection). Probabilities are based on aggregate counts of exposure and deaths across all select ages, and represent the average probability of death within the next year for persons entitled a given number of years. Similarly, aggregate future lifetime represents the average life expectancy of those who have been entitled for a given number of years.

Table 7A and Table 7B show probabilities of death for male and female DI disabled worker beneficiaries with HIV-related impairments, by select age and duration. These tables are similar to tables 1 A and 1B, except that the experience of persons receiving only SSI is excluded.

Table 1A.-Male HIV Disabled Beneficiaries
Probability of Death
(2002-06 Social Security DI and SSI disability experience)

| Select age | Duration of disability |  |  |  |  |  |  |  |  |  |  | Attained age |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | $\begin{aligned} & 10 \text { or } \\ & \text { more } \end{aligned}$ |  |

Notes:

1. Select age denotes age last birthday at entitlement to disability benefits. Duration measured in years since selection. Attained age calculated as sum of select age and duration. Results do not include auxiliary beneficiaries payable under the DI program.
2. The value $q_{[x]+t}$ at duration $t$ represents the probability of death-in a multiple-decrement environment-during the ( $t+1$ ) year of entitlement for those originally entitled to disability benefits at select age $[x]$ who have attained age $[x]+t$.
3. Select-and-ultimate table is read across the row for $0-10$ years since selection, and down the last (ultimate) column for 10 or more years since selection.
4. Where the data are very sparse, particularly for some very young and very old select ages, results are estimated using blending techniques and Whittaker-

Henderson Type B two-dimensional graduation to mitigate the problem. See Appendix A, Section E. for details.

Table 1B.-Female HIV Disabled Beneficiaries Probability of Death
(2002-06 Social Security DI and SSI disability experience)

| Select age | Duration of disability |  |  |  |  |  |  |  |  |  |  | Attainedage |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Notes:

1. Select age denotes age last birthday at entitlement to disability benefits. Duration measured in years since selection. Attained age calculated as sum of select age and duration. Results do not include auxiliary beneficiaries payable under the DI program.
2. The value $l_{[x]}$ at duration 0 represents the assumed number of lives originally entitled to disability benefits at select age $[x]$; the value $l_{[x]}+t$ at duration
$t>0$ represents the number of lives remaining from the original $l_{[x]}$ who have attained age $[x]+t$. Lives are decremented using probabilities from Table 1A.
3. Select-and-ultimate table is read across the row for $0-10$ years since selection, and down the last (ultimate) column for 10 or more years since selection.

Table 2B.-Female HIV Disabled Beneficiaries

## Survival Table

(2002-06 Social Security DI and SSI disability experience)

| Select age | Duration of disability |  |  |  |  |  |  |  |  |  |  | Attained <br> age |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Notes:

1. Select age denotes age last birthday at entitlement to disability benefits. Duration measured in years since selection. Attained age calculated as sum of select age and duration. Results do not include auxiliary beneficiaries payable under the DI program.
2. The value $e_{[x]+t}$ at duration $t$ represents the average number of years of life remaining for those originally entitled to disability benefits at select age $[x]$ who have attained age $[x]+t$. Values are based on survivorship experience from Table 2A.
3. Select-and-ultimate table is read across the row for 0-10 years since selection, and down the last (ultimate) column for 10 or more years since selection.

Table 3B.-Female HIV Disabled Beneficiaries
Expected Future Lifetime
(2002-06 Social Security DI and SSI disability experience)

| Select age | Duration of disability |  |  |  |  |  |  |  |  |  |  | Attained age |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Notes:

1. Select age denotes age last birthday at entitlement to disability benefits. Duration measured in years since selection. Attained age calculated as sum of select age and duration. Results do not include auxiliary beneficiaries payable under the DI program.
2. The value $e_{[x]+t}$ at duration $t$ represents the average number of years of life remaining for those originally entitled to disability benefits at select age $[x]$ who have attained age $[x]+t$. Values are based on survivorship experience from Table 2B.
3. Select-and-ultimate table is read across the row for 0-10 years since selection, and down the last (ultimate) column for 10 or more years since selection.

Table 4.-HIV Disabled Beneficiaries Aggregate Probability of Death and Expected Future Lifetime,
by Select Age by Select Age

Notes:

1. Select age denotes age last birthday at entitlement to disability benefits.
2. Probability of death at select age $[x]$ represents the average probability of death within one year for those originally entitled to disability benefits at that particular age. Values are exposure-weighted averages of the graduated and blended probabilities of death across all durations from Table 1A and Table 1B.
3. Future lifetime at select age $[x]$ represents the aggregate life expectancy in years for those originally entitled to disability benefits at that particular age. Values are exposure-weighted averages of expected future lifetime across all durations from Table 3A and Table 3B.

Notes:

1. Attained age calculated as sum of select age and duration.
2. Probability of death at attained age $x$ represents the average probability of death within one year for those originally entitled to disability benefits who have attained that particular age. Values are exposure-weighted averages of the graduated and blended probabilities of death across all durations from Table 1A and Table 1B. 3. Future lifetime at attained age $x$ represents the aggregate life expectancy in years for those originally entitled to disability benefits who have attained that particular age. Values are exposure-weighted averages of expected future lifetime across all durations from Table 3A and Table 3B.

Table 6.-HIV Disabled Beneficiaries Aggregate Probability of Death and Expected Future Lifetime, by Duration
(2002-06 Social Security DI and SSI disability experience)

| Duration | Male |  | Female |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Probability of death | Future lifetime | Probability of death | Future lifetime |

Notes:

1. Duration measured in years since selection.
2. Probability of death at duration $t$ represents the average probability of death during the ( $t+1$ ) year of entitlement to disability benefits. Values are exposure-weighted averages of the graduated and blended probabilities of death across all ages from Table 1A and Table 1B.
3. Future lifetime at duration $t$ represents the aggregate life expectancy in years for those originally entitled to disability benefits who have not died after $t$ years. Values are exposure-weighted averages of expected future lifetime across all ages from Table 3A and Table 3B.

Notes:

1. Select age denotes age last birthday at entitlement to disability benefits. Duration measured in years since selection. Attained age calculated as sum of select age and duration. Results do not include auxiliary beneficiaries payable under the DI program. Probabilities reflect experience of the DI rolls only. Beneficiaries may be concurrently entitled to DI and SSI benefits, but those entitled to SSI only are not considered.
2. The value $q_{[x]+t}$ at duration $t$ represents the probability of death-in a multiple-decrement environment-during the $(t+1)$ year of entitlement for those originally entitled to disability benefits at select age $[x]$ who have attained age $[x]+t$.
3. Select-and-ultimate table is read across the row for 0-10 years since selection, and down the last (ultimate) column for 10 or more years since selection.
4. Where the data are very sparse, particularly for some very young and very old select ages, results are estimated using blending techniques and WhittakerHenderson Type B two-dimensional graduation to mitigate the problem. See Appendix A, Section E. for details.

Table 7B.-Female HIV Disabled Beneficiaries (DI Program Only)
Probability of Death
(2002-06 Social Security DI disability experience)

| Select age | Duration of disability |  |  |  |  |  |  |  |  |  |  | Attained age |

Notes:

1. Select age denotes age last birthday at entitlement to disability benefits. Duration measured in years since selection. Attained age calculated as sum of select age and duration. Results do not include auxiliary beneficiaries payable under the DI program. Probabilities reflect experience of the DI rolls only. Beneficiaries may be concurrently entitled to DI and SSI benefits, but those entitled to SSI only are not considered.
2. The value $q_{[x]+t}$ at duration $t$ represents the probability of death-in a multiple-decrement environment-during the ( $t+1$ ) year of entitlement for those originally entitled to disability benefits at select age $[x]$ who have attained age $[x]+t$.
3. Select-and-ultimate table is read across the row for 0-10 years since selection, and down the last (ultimate) column for 10 or more years since selection.
4. Where the data are very sparse, particularly for some very young and very old select ages, results are estimated using blending techniques and WhittakerHenderson Type B two-dimensional graduation to mitigate the problem. See Appendix A, Section E. for details.

## Appendix A

## Study Population and Methods

## A. Overview

This study is based on 154,000 records of Social Security Disability Insurance (DI) worker beneficiaries drawn from the administration's Master Beneficiary Record (MBR) as of February 2009, and an additional 98,000 records drawn from the Supplemental Security Record (SSR) as of November 2011. The 5 -year observation period covers January 1, 2002 through December 31, 2006. These records provide 647,000 life-years of exposure for males and 234,000 life-years of exposure for females. The primary variables of interest are: the age at entitlement, the number of years since entitlement, and sex of the beneficiary.

Death is the main cause of termination among beneficiaries with HIV impairments. Benefits may also end because of non-death reasons such as returning to work, conversion to old-age benefits under the DI program, or 12 consecutive months of non-pay status under the SSI program. However, due to the sparsity of such terminations among HIV beneficiaries, these categories are not explicitly examined. The table below provides a breakdown of the termination data collected from the current observation period. For comparison, we also include results from the two prior periods that were analyzed in Actuarial Note \#146.

## Number of HIV Disabled Beneficiaries on the DI and SSI Rolls with Benefits Terminated, by Reason

|  | Male | Female | Total |
| :---: | :---: | :---: | :---: |
| (January 2002-December 2006) |  |  |  |
| Death | 38,968 | 13,774 | 52,742 |
| Non-Death | 12,344 | 4,058 | 16,402 |
| Total | 51,312 | 17,832 | 69,144 |
| (January 1997-December 2001) |  |  |  |
| Death | 44,747 | 13,643 | 58,390 |
| Non-Death | 11,440 | 3,657 | 15,097 |
| Total | 56,187 | 17,300 | 73,487 |
| (January 1992-December 1996) |  |  |  |
| Death | 124,553 | 21,136 | 145,689 |
| Non-Death | 7,259 | 2,450 | 9,709 |
| Total | 131,812 | 23,586 | 155,398 |

Source: HIV database as of June 2011. Results do not include auxiliary beneficiaries payable under the DI program.

## B. Data Considerations

Beneficiaries observed for this study appeared on the DI or SSI rolls sometime during the period 2002-06 because of an HIV-related impairment. An HIV diagnosis code (042, 043, 044) may be listed as either the primary or secondary reason for disability. We also consider beneficiaries who have had an

HIV impairment in the past, but appeared on the rolls during the observation period under another impairment category. However, instances where HIV is present but the applicant is either (1) denied benefits, or (2) initially allowed benefits without HIV being listed as the primary or secondary reason for disability are not captured in the study. A small number of HIV-disabled child and widow DI beneficiaries are also excluded from this study.

Mortality experience is affected by several unique circumstances. Since experience begins with entitlement, deaths that occur during the 5 -month waiting period prior to entitlement to DI benefits are outside the scope of this study. It is also true that a claimant may die in the first month of entitlement, or before final disposition of the disability claim-in which case only retroactive disability benefits may be payable. No exposure is credited in these instances, although death is counted. Note that the SSI program does not have a waiting period and SSI-only recipients come under observation as soon as eligibility is determined.

In general, we observe study participants through the end of the duration in which benefits are terminated or, if earlier, through the end of the observation period. As previously mentioned, non-death termination can occur when a beneficiary returns to work, or remains in non-pay status for 12 consecutive months under the SSI program-for example, due to excess income or resources. Under the DI program, disabled workers have the option to convert to old-age benefits anytime after age 62 . Mandatory conversion takes place at normal retirement age. DI benefits are terminated upon conversion as the OASI Trust Fund begins to pay old-age benefits. However, in this study we continue to observe beneficiaries beyond the time of conversion. So, to a certain extent, this study traverses the activity of the OASI rolls by tracking deaths of former disabled workers who convert to old-age benefits. The SSI program has an aged category for non-disabled individuals whose eligibility requires them, in part, to be age 65 or older. However, there is no automatic conversion to this category. Impaired beneficiaries continue to be considered disabled beyond this age, and also continue under observation in this study.

Other exceptional cases exist where observation continues beyond non-death termination of benefits. This occurs for some SSI-only cases in which the SSR is automatically annotated upon reporting of death. Instances where death is recorded after non-death termination may result in additional exposure credited to an otherwise terminated recipient. However, this anomaly does not materially impact results.

This study integrates a special longitudinal file constructed from the SSR. However, due to the nature of the data, several problems were encountered in combining MBR records with SSR records relating to individuals who receive both DI and SSI benefits during a period of disability. Dates of DI entitlement and termination from the MBR are used to calculate exposure for concurrent cases. Although these dates capture exposure for overlapping periods of DI and SSI eligibility, they do not capture exposure for periods outside DI entitlement. So cases where SSI-only benefits are paid during any part of the 5-month waiting period will not have exposure for those months counted. Also some exposure may not be captured for beneficiaries who transition from concurrent status to SSI-only eligibility, due to SGA earnings after the 36-month DI extended period of eligibility. In such cases, observation ends upon termination of DI benefits as a result of work activity. However, SSI eligibility may continue if earnings are such that countable income does not exceed the applicable Federal SSI benefit rate. It should be noted, however, that the above omissions do not materially impact results. Refer to Appendix B for details on SSI considerations.

Another problem involves beneficiaries having multiple records on the SSR. It is possible that different records are related to different impairments. For example, an SSI beneficiary might have several records of eligibility; at least one of which, but not necessarily all, are related to HIV impairments. Given the structure of the longitudinal file, it may not be possible to distinguish which records in multiple-record cases are relevant to the study and which are not. In some instances, non-HIV related periods of disability may be included in the study.

## C. Methods

The availability of complete data on each person in the study (sex, date of birth, date of entitlement, date of decrement, and cause of decrement) allows for direct estimation of the multi-ple-decrement probabilities $q^{(i)}$, where $i$ represents the cause of decrement. Each unit age interval ( $x, x+1$ ] represents one life-year of potential exposure. For each interval that an individual is under observation, the person enters the interval at age $x+r(0 \leq r<1)$, and is scheduled to exit the interval at age $x+s(0<s \leq 1)$. Note that $r=0$ except for instances where the beginning of the observation period falls within the age interval. Similarly $s=1$ except for instances where the end of the observation period falls within the interval. Clearly, $s-r$ is the amount of time that the person is scheduled to be exposed to the risks of decrement. The total scheduled exposure for an interval is obtained by summing over all persons. ${ }^{11}$

As an example of the above method, consider a disabled worker entering an interval at age $x+r$. The scheduled ending age, $x+s$, is established for the interval under the expec-

[^8]tation that the person will either survive to the end $(s=1)$, or exit the study due to the end of the observation period $(s<1)$. Scheduled exposure is then credited as follows: if the person survives to the end of the interval, then exposure is credited from $x+r$ to $x+1$; if the person dies or recovers during the interval, exposure is still credited from $x+r$ to $x+1 ;^{12}$ if the observation period ends during the interval, then exposure is credited from $x+r$ to $x+s$. A modification is made to the way exposure is calculated for determining recovery probabilities. Since recovery is no longer a consideration after converting to old-age benefits, exposure is credited only up until the month of the switch.

Multiple-decrement probabilities are calculated by dividing the observed number of deaths or recoveries in an interval by the aggregate scheduled exposure for that interval. As previously noted, recovery rates are not analyzed in this study.

## D. Select Age and Exposure

This is a select-and-ultimate study with a 10 -year select period implying that the risks of decrement for beneficiaries 10 or more years beyond selection are no longer a function of select age, but a function of attained age only.

Rarely does entitlement to disability benefits occur on a beneficiary's birthday. To facilitate exposure calculations, insuring age and the corresponding insuring date of birth may be substituted for the actual age at entitlement and the actual date of birth, respectively. This study uses an insuring age that is set at the beneficiary's age last birthday as of entitlement. As an example:

```
Date of entitlement: February 1, }200
Date of birth: July 10, }196
Actual age at entitlement: }44\mathrm{ years, }206\mathrm{ days
Insuring age (also select age): 44 years
Insuring date of birth: February 1, 1961
```

Use of insuring age results in an integral select age at entitlement, ensuring that subsequent durations begin on the beneficiaries birthday. This is true whether the participant enters the study during the observation period, or is already part of the entitlement group when the observation period opens.

## E. Duration and Graduation

The unit intervals for which a beneficiary is under observation are called durations. For each select age $[x]$ and duration $n$, the quantity $s-r$ represents the amount of exposure contributed to the observation interval $([x]+n,[x]+n+1]$. For durations beyond the 10 -year select period, exposure is credited to the appropriate attained age interval $(x+n, x+n+1]$.

[^9]Most of the probabilities developed for this study are reported as "raw" (ungraduated) values. However in cells with very little exposure, particularly those for young ages, the results are not a reliable measure of mortality. We sought to mitigate the problem caused by lack of data by using blending and graduation techniques. ${ }^{13}$

Although HIV disability beneficiaries may live to older ages, current administrative records show very little evidence of survival beyond age 75 . Therefore, no results are presented beyond this attained age.

## F. Survival Tables

Survival tables 2A and 2B are constructed from select-andultimate death probabilities. The values $l_{[x]}, l_{[x]+1}, \ldots, l_{75}$ are first calculated for select age $[x]=18$, using a radix of 100,000 . This step determines values for the ultimate period of the table. Values for select ages $[x]>18$ are then derived from the ultimate values by working backwards. For example, $l_{[x]}$ is determined from $l_{x}+10$ using the survival probabilities of the select period for the given select age. The value for $l_{[x]+t}$ is the number of lives remaining from the original $l_{[x]}$ who have attained age $[x]+t$. The number alive at any given select or attained age is not an actual count of disability beneficiaries, but is the product of combining probabilities with an arbitrary radix.

The survival tables are read across the row, or select period, for $0-10$ years since selection, then down the last column, or ultimate period for 10 or more years since selection. The example below uses numbers from Table 2A for male beneficiaries disabled at select age 30 .

| Years since <br> entitlement | Number <br> living | Probability of <br> survival | Attained age |
| ---: | ---: | ---: | ---: |
| 0 | 64,898 | 1.000 | 30 |
| 1 | 58,951 | .908 | 31 |
| 5 | 46,937 | .723 | 35 |
| 10 | 36,403 | .561 | 40 |
| 15 | 28,594 | .441 | 45 |

## G Expected Future Lifetime

Expected future lifetime tables are derived from the survival functions described above using basic actuarial principles found in any standard actuarial text on life contingencies. We also present the results of aggregating over duration, by select age (see Table 4) or attained age (see Table 5).

[^10]Expected future lifetime for a specific select age is an expo-sure-weighted average of the expected future lifetime at each duration of that age. This differs from the expected future lifetime for a specific attained age, which is an exposureweighted average of the expected future lifetime of various select ages at various durations.

For example, expected future lifetime for select age 40 is a weighted average of the expected lifetimes shown across the select row and down the ultimate column. In this instance, each cell represents a different attained age. In contrast, expected future lifetime for attained age 40 is the average of the expected lifetimes for a select 40 -year-old at duration 0 , a select 39 -year-old at duration $1, \ldots$ a select 18 -year-old at duration 22 -all of whom are attained age 40 .

## H. Probabilities and Absolute Rates

The data for this study were collected in a multiple-decrement environment, however, we explicitly consider only two major decrement classes-death and non-death. The symbol $q^{(d)}$ represents the probability of death in the presence of other decrements and is defined as follows:

$$
q_{X}^{(d)}=\int_{0}^{1} p_{x}^{(\tau)} \mu_{x+t}^{(d)} d t
$$

where $p^{(\tau)}$ is the probability of surviving under all decrements; and $\mu^{(d)}$ is the force of mortality.

For each cause of decrement in a multiple-decrement model, it is possible to associate a single-decrement rate that depends only on a particular cause of decrement. The symbol $q^{(d)}$ represents the single-decrement (absolute) rate of death and is defined as follows:

$$
q_{X}^{\prime(d)}=\int_{0}^{1}{ }_{t} p_{x}^{\prime(d)} \mu_{x+t}^{(d)} d t
$$

where $p^{\prime(d)}$ is the probability of not dying. In this representation, beneficiaries who decrement for causes other than death are "taken out" of the total number exposed. Observation stops at the point of non-death decrement resulting in total exposure which is somewhat less than that used in formulating death probabilities. Absolute rates are not presented in this study. ${ }^{14}$

[^11]
## Appendix B

## Disability Program Overview

## A. Definition of Disability

For purposes of entitlement to DI benefits, disability is defined as the inability to engage in any substantial gainful activity (SGA) by reason of any medically determinable physical or mental impairment. The impairment must be expected to result in death or to last for a continuous period of at least 12 months, and must prevent the claimant from performing previous work, or any other kind of work in which a significant number of jobs exist.

The formal determination of disability is based on a five-step sequential evaluation process defined in regulations. The first step compares actual earnings to a specified level to determine ability to engage in SGA. Absent such earnings, the sequential process continues with an evaluation of the nature and severity of the alleged impairment, followed by consideration of age, education, and work experience.

The same definition of disability applies when determining eligibility of adults under the SSI program as described under title XVI of the Social Security Act. This means-tested cash benefits program is also administered by the Social Security Administration.

Special provisions exist for the evaluation of insured status and disability in cases of statutory blindness.

## B. Disability Insured Status and Waiting Period

To be insured for DI benefits, a worker must earn a requisite number of quarters of coverage, or credits in employment covered by Social Security. ${ }^{15}$ To be considered for disability benefits, a worker must be disability insured. This requires having obtained a specific number of credits in recent quarters, as well as enough total credits to be fully insured-at least 6 and no more than 40 credits are required for fully insured status. ${ }^{16}$ The number of required recent credits varies by age, and ranges from 6 out of the last 12 quarters immediately preceding the onset of disability, to 20 out of the last 40 . There is no insured status requirement for disability benefits under the SSI program.

There is a required waiting period for DI benefits, which consists of 5 consecutive full calendar months beginning with the earliest calendar month throughout which the worker satisfied both the disability insured requirements and definition of dis-

[^12]ability. Benefits are not payable during this period. By law, the waiting period is waived for individuals who had a prior period of disability which ended within 5 years of the current period of disability. There is no waiting period for disability benefits under the SSI program.

## C. Substantial Gainful Activity (SGA)

Substantial work activity involves doing significant physical or mental activities; gainful work activity is done for pay or profit. The degree to which an impairment limits an individual's ability to perform basic work activities is essential in determining the severity of the disability.

Certain earnings criteria have been established as reasonable indications of whether an individual is engaging in SGA. The dollar amount associated with defining SGA was originally set at $\$ 100$ at the inception of the DI program. This amount was updated on an ad hoc basis until 2001, at which time the amount became subject to the annual increase in average wages. As of 2012, an employee earning over $\$ 1,010$ per month will ordinarily demonstrate SGA; less than that amount will ordinarily demonstrate lack of SGA.

## D. Impairments

To establish a disability, claimants must provide sufficient evidence of any medical condition in the form of symptoms, clinical signs, and laboratory findings. To determine the severity of the disability, SSA consults the Listing of Impairments, which sets forth the criteria needed to be met by various impairments in order for the claimant to be judged incapable of performing SGA. The listings are a set of medical evaluation criteria in the Federal regulations that describe physical and mental conditions which are so severe that it is presumed that individuals whose medical conditions meet or equal these criteria are disabled regardless of their age, education, or work experience.

Many individuals are found to be disabled even though impairments fail to meet the level of severity detailed in the listings. In these cases, an individual's medical condition is evaluated in conjunction with age, education, and job skills. These vocational factors are given increasing weight with the advancing age of the worker, and are particularly significant in determining disability among workers age 50 or older.

## E. Determination and Appeals Process

Regulations describe the process of administrative review performed by the Disability Determination Services (DDS) and the Office of Disability Adjudication and Review (ODAR). The DDS is responsible for developing medical evidence and rendering the initial determination of whether the
claimant is disabled or blind under the law. If dissatisfied with the initial DDS decision, the claimant has the right to request further administrative review by the DDS, ODAR, and beyond to the federal courts.

Many factors exist that affect the number of disability claims filed as well as the rate at which these claims are allowed or denied. However, the impact of any one factor is difficult to gauge. In general, economic, demographic, and administrative factors all have a direct effect on the size and scope of the DI program. ${ }^{17}$

## F. SSI Considerations

The SSI program provides assistance to individuals who are either ineligible for Social Security benefits, or whose benefits may not provide a basic level of income. This "last resort" type of assistance is available to aged, blind, or disabled individuals whose income and resources are below specified lev-

[^13]els. The program takes into account all income and resources that an individual has and applies uniform standards and objective eligibility criteria to measure the need for assistance. These include:

- Medical determination of disability and blindness equivalent to that used by the DI program. ${ }^{18}$
- 65 as the minimum age requirement for assistance based on age.
- A limitation on the amount of income-including any Social Security benefits-and resources that an individual can have and still qualify for SSI benefits. ${ }^{19}$

[^14]
[^0]:    ${ }^{1}$ See Actuarial Note \#146 at www.ssa.gov/OACT/NOTES/n2000s.html for details.

[^1]:    ${ }^{2}$ The ICD series was converted under Tenth Revision to B20-B24, effective 1998. The ninth revision remains the basis for SSA HIV codes.

[^2]:    ${ }^{3}$ A group of common complications found in early stage HIV infection was categorized as AIDS-Related Complex. Individuals may have exhibited serious impairments that were reasonably assumed to be related to the infection, but did not have a definitively diagnosed case of AIDS. Symptoms include unexplained chronic deficiency of white blood cells, poorly functioning lymphatic system, fungus infection of the mouth, herpes, recurrent fever, prolonged diarrhea, or presence of HIV antibodies.
    ${ }^{4}$ Refer to Appendix B for an overview of the definition of disability and the determination process.

[^3]:    ${ }^{5}$ Estimates from memorandums Estimated Number of DI Beneficiaries and Amount of Benefit Payments Due to HIV/AIDS (Zayatz, July 2012), and Estimated Impact of the HIV Pandemic on Federal SSI Payments and Federally Administered SSI Caseloads (Moroz, July 2012).
    ${ }^{6}$ For further insight, refer to the CDC annual HIV Surveillance Report at www.CDC.gov website. CDC provides annual compilations of State HIV surveillance data and Federally mandated AIDS reports. This national report on cases of HIV infection and AIDS in the United States is used by CDC's public health partners and professionals in other Federal agencies, health departments, and academic institutions.
    ${ }^{7}$ The first person-based mortality study of HIV beneficiaries covered two separate 5 -year periods: 1992-96 and 1997-2001. For a complete discussion on these earlier periods, refer to Actuarial Note \#146 Death Termination Experience for DI Disabled Workers and SSI Disabled Adults with HIVRelated Impairments (Barrick and Zayatz, June 2005) www.ssa.gov/OACT/ NOTES/n2000s.html

[^4]:    ${ }^{8}$ HIV Surveillance Report (2009, Vol.21) www.CDC.gov
    ${ }^{9}$ Totals include beneficiaries concurrently entitled to DI and SSI benefits, but do not include beneficiaries entitled to SSI only.
    ${ }^{10}$ Total includes SSI-only recipients, as well as a small percentage entitled only to Federally administered State Supplementary SSI payments.

[^5]:    ${ }^{11}$ Findings are based on comparisons with overall disability mortality tabulated for the period 2001-05 in Actuarial Study \#122: Social Security Disability Insurance Program Worker Experience (Zayatz, May 2011) www.ssa.gov/ OACT/NOTES/actstud.html

[^6]:    Notes:

    1. Select age denotes age last birthday at entitlement to disability benefits. Duration measured in years since selection. Attained age calculated as sum of select age and duration. Results do not include auxiliary beneficiaries payable under the DI program.
    2. The value $q_{[x]+t}$ at duration $t$ represents the probability of death-in a multiple-decrement environment-during the $(t+1)$ year of entitlement for those originally entitled to disability benefits at select age $[x]$ who have attained age $[x]+t$.
    3. Select-and-ultimate table is read across the row for $0-10$ years since selection, and down the last (ultimate) column for 10 or more years since selection.
    4. Where the data are very sparse, particularly for some very young and very old select ages, results are estimated using blending techniques and WhittakerHenderson Type B two-dimensional graduation to mitigate the problem. See Appendix A, Section E. for details.
[^7]:    Notes:

    1. Select age denotes age last birthday at entitlement to disability benefits. Duration measured in years since selection. Attained age calculated as sum of select age and duration. Results do not include auxiliary beneficiaries payable under the DI program
    2. The value $l_{[x]}$ at duration 0 represents the assumed number of lives originally entitled to disability benefits at select age $[x]$; the value $l_{[x]+t}$ at duration $t>0$ represents the number of lives remaining from the original $l_{[x]}$ who have attained age $[x]+t$. Lives are decremented using probabilities from Table 1B. 3. Select-and-ultimate table is read across the row for $0-10$ years since selection, and down the last (ultimate) column for 10 or more years since selection.
[^8]:    ${ }^{11}$ For a complete discussion, refer to chapter 6 of Survival Models and Their Estimation (London 1988, second edition).

[^9]:    ${ }^{12}$ All persons are expected to survive to the end of the interval, even those who wind up dying or recovering at age $x+t \leq x+s$. The important point is that decrement was not expected so the scheduled ending age is set at $x+1$.

[^10]:    ${ }^{13}$ Estimation techniques were used with "cells" having roughly 50 or fewer life-years of exposure. The horizontal and vertical smoothing coefficients of two-dimensional Whittaker-Henderson Type B graduation were chosen to obtain some degree of smoothness within both individual durations (columns) and select ages (rows). For details, refer to Graduation: The Revision of Estimates (London 1985).

[^11]:    ${ }^{14}$ For a complete discussion on multiple-decrement probabilities and associated single-decrement rates, the reader is referred to chapter 10 of Actuarial Mathematics (Bowers et al. 1997).

[^12]:    ${ }^{15}$ In 2012, a worker receives one credit (up to a maximum of four) for each $\$ 1,130$ of annual covered earnings. This amount is indexed each year by the increase in average wages.
    ${ }^{16}$ A fully insured worker has at least one credit (whenever acquired) for each year starting with the year the worker attains age 22 and ending with the year before the year the worker attains age 62, becomes disabled, or dies (whichever occurs earliest) - credits are not required for years that are partially or fully within a period of disability.

[^13]:    ${ }^{17}$ Some of the determinants which may have a significant impact on both the number of claims filed and the rate of favorable determinations are discussed in detail in Actuarial Study \#122: Social Security Disability Insurance Program Worker Experience (Zayatz, May 2011) www.ssa.gov/OACT/NOTES/ actstud.html

[^14]:    ${ }^{18}$ Note that under SSI, there are no requirements relating to disability insured status or waiting period as set forth by the DI program.
    ${ }^{19}$ The countable income limits for individuals and couples are equal to their respective Federal benefit rates and are increased annually according to changes in the cost of living. Effective January 1, 2012, the Federal benefit rate is $\$ 698$ a month for individuals and $\$ 1,048$ a month for couples. The resource limit is $\$ 2,000$ in countable resources for individuals and $\$ 3,000$ for couples. For further details in areas such as income and resource exclusions and interaction with benefits from Social Security and other Federal or Statesponsored programs, refer to the Annual Report of the Supplemental Security Income Program www.ssa.gov/OACT/SSIR
